Description:

Coastal communities are exposed to numerous climate-related hazards, all of which are projected to increase in intensity and frequency in the coming decades. The way these hazards are experienced depends on a variety of factors that make coping with and recovering from natural hazards more difficult for some communities than others. Maryland faces growing pressure from water hazards, including storm surge, sea level rise, and stormwater. With its extensive coastline, the Chesapeake Bay makes managing floodwaters a key priority moving forward. The varied and dense populations on the Western Shore mean that the intersection of multiple vulnerabilities and climate hazards presents a high risk of cascading and compounding hazard events.

This dataset includes census block group level component scores of various indices from the National Centers for Coastal Ocean Science (NCCOS) Community Risk Assessment of Flooding and Heat Hazards in Baltimore, MD. Indices included in this archived dataset include SoVI[®], ecosystem services valuation, structural exposure, urban heat hazard, and flood hazard. Each component score is aggregated to the block group level geography provided by the U.S. Census Bureau. Additionally, intermediary raster-based datasets on stormwater flooding hazard are provided, as well as spatial data on wetlands and protected areas.

Methods:

This assessment uses a geospatial, indicator-driven approach to integrate data from a variety of sources related to community risk in Baltimore, MD and the surrounding 5 counties of Baltimore, Harford, Howard, Anne Arundel, and Queen Anne's. SoVI[®] was derived from Census data and applied to each

block group. Stormwater flooding potential was calculated using an application of the “FIGUSED” methodology based on locally relevant datasets. This methodology incorporates seven indicators frequently used to identify areas of high flooding potential. These indicators are: “F” – flow accumulation, “I” – rainfall intensity, “G” – geology (hydrologic soil groups), “U” – land use, “S” – slope, “E” – elevation, and “D” – distance from the drainage network. For each of these indicators, a value of 1 corresponds to higher flood potential, while values closer to zero (or null) correspond to lower flood potential. The final raster dataset ranges from 0-7, and all data were resampled to a 30 meter resolution grid and also applied to each block group. A structural exposure index was calculated by aggregating each contributing indicator to the block group. An ecosystem service value index was created by averaging a total ecosystem service valuation model across each block group. Sea level rise projections and storm surge estimates from the National Oceanic Atmospheric Administration were calculated at the block group level. An urban heat index was derived using a combination of sensor data from Johns Hopkins University (for Baltimore City) and remotely sensed data, in conjunction with land use/land cover data, for suburban and rural areas. Both raster and block group aggregations are available. Additionally, data on wetland extent and protected areas are included in the archival package.

For full dataset methods please see the NOAA Technical Memorandum NOS NCCOS *report forthcoming*

Table 2: RA2_MD_Data_Dictionary_Archived_Raster_Data.csv

Variable	Filename	Definition	Units	Range	Resolution
Stormwater flooding potential index raster	SW_index	Stormwater potential flooding index based on the FIGUSED methodology that incorporates flow accumulation, precipitation, hydrologic soil groups, land use-landcover, slope, elevation, and drainage density. Higher values indicate higher stormwater potential flooding.	Continuous raster	0-7	30m
Flow accumulation	FLOW_FIGUSED	Flow accumulation data derived from digital elevation model (DEM) used in calculation of overall stormwater flooding potential index. (normalized 0-1)	Continuous raster	0-1	30m
Precipitation	PRISM_FIGUSED	Global Gridded Standardized Precipitation Index (SPI) from PRISM climate group, annual precipitation 30 year normals used in calculation of stormwater flooding potential index. (normalized 0-1)	Continuous raster	0-1	30m

Data Documentation
NCCOS Community Risk Assessment: RA2 MD

Geology (hydrologic soil groups))	GEO_FIGUSED	Hydrologic soil group raster, using soil data from the USDA National Resources Conservation Service Soil Survey. Soil hydrologic groups A and B (indicating well-drained soils) were assigned a value of 0, while areas falling into groups C, D, A/D, B/D, and C/D were given a value of 1, indicating a higher flood potential. This was an input in the final stormwater flooding potential index.	Categorical	0-1	30m
Land use	LULC_FIGUSED	Resampled 1 meter resolution data to 30 meter raster categorized into 2, 4, 6, 8, and 10 based on contribution to stormwater flooding potential index.	Categorical	1-10	30m
Slope	SLOPE_FIGUSED	Slope was derived from the input Digital Elevation Model (DEM) used in the calculation of stormwater flooding potential index. (normalized 0-1)	Continuous raster	0-1	30m
Elevation	DEM_FIGUSED	Digital Elevation Model (DEM) used in calculation of stormwater flooding potential index. (normalized 0-1)	Continuous raster	0-1	30m

Data Documentation
NCCOS Community Risk Assessment: RA2 MD

Proximity to drainage networks	DRAINAGE_FIGUSED	Drainage network density grid created using flowline data from the National Hydrology Dataset. (normalized 0-1). This was an input to the final stormwater flooding potential index.	Continuous raster	0-1	30m
Urban Heat Index	URBAN_HEAT_INDEX	Urban heat index calculated from remotely sensed data from the Landsat 8 program. Data contains relative heat on a scale of 1 (mild) to 5 (severe).	Categorical raster	0-5	30m
